433 ours, as we saw. In short, these are agricultural Indians and their hunting has more the aspect of a diversion than of a gainful occupation.

411
177 They claimed to have about fifteen shotguns in the tribe, but most of these are probably never fired. We saw two or three, old muzzle-loaders traded in from Brazil, the Guianas, or northern Venezuela. Practically all the Indians of this general region acquired a few guns long ago, before any civilized persons had ever visited them, but powder and shot have always been rare and expensive and the guns are reserved for great occasions or are articles of pure luxury. They have never become every-day weapons.

murun-yɛ'), long cane (purau-yɛ') shaft, with a short notched hardwood (murun-yɛ') plug or nock at the butt. The three joints are carefully wrapped with thread coated with beeswax. The foreshaft is commonly painted with a reddish gum on which a crude serpentine design may be traced with a finger while it is still wet. A typical specimen is 148 cm. in length: point 4 cm., point-foreshaft wrapping 7 1/2 cm., foreshaft 21 cm., foreshaft-shaft wrapping 4 1/2 cm., shaft 107 1/2 cm., and string-plug and its wrapping 3 1/2 cm. The center of gravity is 92 cm. from the butt end — relatively farther forward than in the purau, which is feathered while the panachika is not.

The supalari (Fig. 16A) is like the panachika but is somewhat stouter, with a much heavier point, also steel but lanceolate and not barbed. This is the big-game arrow. The foreshaft is short but stout and there may be supplementary strings running from the point-foreshaft to the foreshaft-shaft wrappings. A specimen measures 155 cm. in length: point 6 1/2 cm., point-foreshaft wrapping 3 1/2 cm., foreshaft 9 1/2 cm., foreshaft-shaft wrapping 6 cm., shaft 126 1/2 cm., string-plug and wrapping 3 cm. The center of gravity is 100 1/2 cm. from the butt, still farther forward than in the panachika (the foreshaft is shorter but heavier and the point is longer and heavier).

The fourth type of arrow, waibakasi[112] (Fig. 16C) is mechanically the most complex. It has the same parts as the panachika and supalari, with a relatively very long foreshaft and stout shaft, but the point is detachable. The point proper is of steel and shaped as in the panachika, but this is continued in two posterior prongs around which a hollow core is built with kurawai' string and balata. This core slips loosely onto the sharpened end of the wooden foreshaft and is held there by a loop of heavy cord inserted into the wrappings of the hollow core and looped around the foreshaft about 20 cm. posterior to this insertion. In use a light cord several meters long is attached to this loop and its end held in the left hand. The arrow is used for shooting large fish. When the point penetrates the fish, the loop slips off the foreshaft, the arrow floats away, and leaves the point in the fish and attached to the line held by the shooter. A specimen is 173 1/2 cm. long, including the point, 167 1/2 cm. without the point. The point alone is 7 1/2 cm. from tip to base of core, 8 cm. to end of prongs, of which 3 1/2 cm. is the bare unwrapped point. Foreshaft 55 1/2 cm., foreshaft-shaft wrapping 6 cm., shaft 101 1/2 cm., string-plug and wrapping 4 1/2 cm. The center of gravity (with point in place) is 103 cm. from the butt, relatively more posterior than in the panachika or supalari but less so than in the feathered tarau.

The waibakasi is different from anything that I find described among the most nearly neighboring or related Indians and my Taurepán informants had never heard of the object or its name, but it is known among the Makuchi and is widespread in British Guiana (Roth). The other three types of arrows are in general use among neighboring Carib tribes.[113] There are at least three types

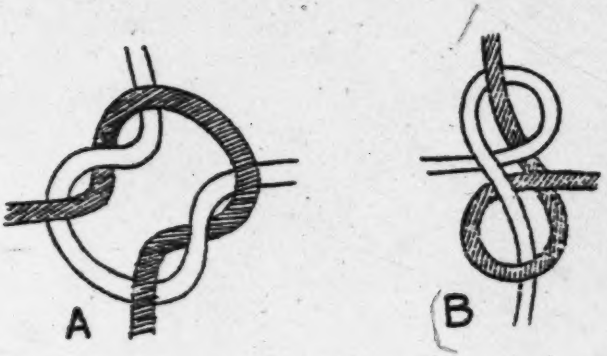

Fig. 45 — Kamarakoto Netting Knots.
A, B, the two usual types of knots used in making nets like those of Fig. 18. One thread is shaded for clarity. They are, of course, identical in character in the actual fabric and the knot is pulled tight.

286 alternating the patterns a varied design can be produced, often with very artistic effect. A favorite pattern is woven mainly in one-over-two, with numerous narrow transverse bands of two-over-two, often winding up at the lock or crosstie with wider sections of tightly woven two-over-two.

[854] [822] [439] The finished baby sling (Fig. 43 B) is sometimes left white (a color it does not retain) and sometimes dyed pink or red. The Taurepánes obtain brightly colored thread by unraveling trade hammocks from Brazil and by tying some of these into their own white thread, they make baby slings with varicolored diagonal bands, but the Kamarakotos do not do this and it is probably another neomorph arising from the adaptation of a foreign material to a native technique.

The fourth thread textile technique may be called one-needle crocheting, because it is composed of interlocking loops of thread made with the aid [171] of a single hooked needle.[144] This art, no less peculiar than loom-plaiting, is also widespread, although apparently less so, and aside from the Arekunas is known among the Makuchis, Akawais, "Caribs" (probably Kalíñas), and perhaps a few other tribes. Articles as made by the Kamarakotos are more even and tight in mesh and more skillfully designed and finished than any I have seen, or seen illustrated, made by other Indians and it may be claimed that the Kamarakotos have brought this art to its highest development.

286 413 177 The needle used may be and doubtless formerly always was a wooden pin with a hook carved at the end. Now a large wire nail with the tip bent and filled to make a smooth hook is preferred and most of the women have such

534 dancing, but a legend suggests its connection with magic, a connection which
535 Izikowitz believes to have been involved in the spread of this instrument. In
773 this legend a maraka appears as a magical instrument the sounding of which
224 causes peccaries, the favorite prey of hunters, to appear. In fact the use of the rattle in dancing is probably connected with this sort of hunting magic, although the connection is not now clearly recognized by the Indians.

534 3. The Kamarakotos make drums (Fig. 68) of various sizes but all are constructed in the same way and all are light and portable so that the player can carry one and dance at the same time. The kettledrum and the tubular (open bottom) drum are unknown, only the two-headed form being used. The body is made of a section of a tree trunk (a white, soft, unidentified wood) of appropriate diameter, with the center hollowed out. A single round hole is
[237] made in the side as an air vent. The drumheads are made of hide, deer, lapa, peccary, etc., — a specimen has deerskin on one end and peccary on the other and apparently any hide of proper size is used indiscriminately. The hair-side is out on the finished drum but the hair is removed from the exposed surface.
● [289] The skin is lashed by spiral curagua windings to a liana hoop of proper size to fit snugly on the drum body onto which it is slipped. It is held in place and the drumhead stretched by placing a second hoop distal to it (nearer the end of the drum) on each end and these tightening hoops, which are not fastened to the drumhead or body, are drawn toward each other by a crisscross lashing of heavy cords. Where these cross, at the middle of the side of the drum, a circular lashing of the same cord is fastened and from this a carrying cord projects, which may be made into a loop by tying its end to one of the lashings. The drum is carried in one arm and played with a single stick held in the other hand.

114 The origin and distribution of drums in South America have given rise
171 to extensive discussion, most of which is adequately summarized by Izikowitz.
174 The pre-Columbian distribution cannot now be exactly reconstructed except
534 that it was certainly wide. The kettledrum is the oldest and from it an open-bottomed drum developed in Mexico and Central America. It was formerly supposed that two-headed drums were all post-Columbian but Izikowitz has shown that such drums are indigenous at least in Peru and adjacent regions. On the other hand Izikowitz agrees with most previous students in concluding that the drum was unknown in northeastern South America (Amazonia, the Guianas, Venezuela, and the West Indies, at least) until introduced by Europeans. Only a few students have ventured a contrary opinion, for example, Williams says of the Makuchi word sanbura, "This may perhaps be a native word as the drum must have existed before the advent of Europeans." Roth has pointed out apparently conclusive evidence that the first Europeans, including Columbus himself, found single-membrane drums in use in the West Indies, evidence apparently overlooked by Izikowitz. A few early travelers in the Guianas and in Amazonia also mention what seem to be one-membrane drums

534
284

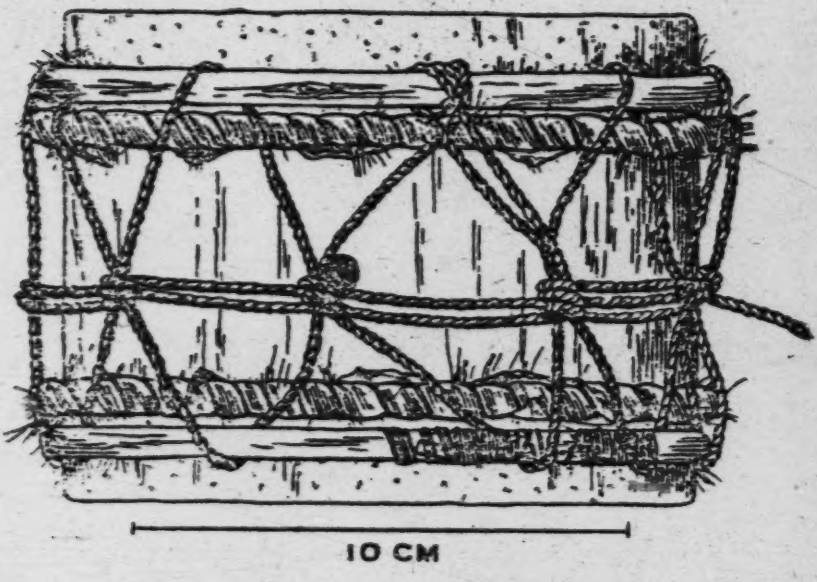

Fig. 68 — Kamarakoto Drum.
A small hand drum such as is carried by the drummer in a parichara dance. Drums up to twice this size or rather more are made in essentially the same way.

[535]

114 (see Roth) but these observations are too recent to exclude indirect European
171 influence, improbable as this is for drums of such a typically American sort.
174 Roth concludes that the double-membrane drum was probably not European but
534 introduced from North America (i.e. inferentially from the North American Indians) but after the European invasion, a conclusion that has not been accepted and that is not very seriously supported by any cogent evidence.

The evidence that the drum is not indigenous in this area is chiefly that it shows almost unmistakable European influence in the usual method of lashing and that over this whole area, regardless of linguistic stocks, it is called by names which, despite Williams' doubts, are almost certainly derived from the Spanish or Portuguese, of which the Kamarakoto word sambura is typical.

This evidence proves that the drums of this region show some, perhaps only indirect, European influence. They do not prove that the drums are of European origin or that they are not derived by post-Columbian evolution from an indigenous drum. Izikowitz, himself, concludes that the essentially similar drums of the Chipayas (southwestern Bolivia) are modified derivatives of pre-Columbian drums and he also notes the difficulty of being sure that a European
